

## What is our GOAL for this MODULE?

The goal of this module is to learn the concept of inheritance to create objects with properties of parent class.

## What did we ACHIEVE in the class TODAY?

- Added an image property to one of the classes and used it to make one of the game objects animated.
- Introduced the concept of inheritance and how a subclass can inherit the properties and functions of a parent class.
- Wrote a subclass which extends the properties and functions of a parent class.
- We revised the following as well:
  - A class is a blueprint of an object.
  - A class contains defined properties(like width, height) and functions (like display()).
  - A class is used to create one or more objects having the same properties and functions as defined in the class.

# Which CONCEPTS/ CODING BLOCKS did we cover today?

• The concept of inheritance

#### How did we DO the activities?

1. The Bird class blueprint had properties like body, width, and height. We added an additional property to it called image and loaded the bird image.

- 2. We wanted an image instead of a rectangle. We used the image() instruction instead of the rect() instruction.
  - The first argument was for the image.
  - The second and third arguments were for the position. We changed the position to where we wanted and used 0, 0.
  - The fourth and fifth were for the width and height and we used it from the

```
class Bird {
                          constructor(x, y) {
                                         var options = {
                                                       'friction': 1.0,
                                                         'restitution':0.5
                                                                                                                                                                                                                        ALL MANAGER STATES OF THE STAT
                                        this.body - Bodies.rectangle(x, y, 50.
                                        this width - 50:
                                        this.height - 50;
                                        this.image - loadImage("sprites/bird.
                                       World.add(world, this.body);
                          display(){
                                        var pos = this.body.position:
                                       pos_{x} = mouseX;
                                      pos.y = mouseY:
                                        var angle = this.body
                                         rotate(angle)>
```

property of

the class (defined in the constructor).

In programming language, we have a concept of a Parent / Base class and Children / Sub classes. Children/Sub classes that are created using Parent / Base class inherit all the properties and functions from the parent class.

3. We wrote the code to create a BaseClass. Our Base object can have all the properties and functions which we had in the Bird class.

```
Class is 🕨 🍖 BaseClass 🕨 💌 constructor
class BaseClass{
    constructor(x, y, width, heigh
         var options = {
        this body - Bodies
                                               width, height, options):
        this.width - width;
this.height height;
        this.image - loadImage(
                                      ites/base.png"):
        World add (world,
      display(){
        var angle = this.body.angle;
        translate(this.body.position.x, this.body.position.y);
        rotate(angle);
        imageMode(CENTER);
        image(this.image, 0, 0, this.width, this.height):
```

4. Included the src of the BaseClass in the index.html file.

Box and the Pig classes were very similar to the BaseClass. These classes became the child class for this parent BaseClass and inherited all the properties and functions. All the properties and functions of a parent class were present in the child class.

5. We created a child Bird Class which inherited all the properties and functions of our BaseClass.

6. Finally, we added the bird image to the bird class constructor as well. You could do it inside the constructor and overwrite any of the properties of the parent class inside the child class and change it.

7. To override the display function of the base class by writing code for it, we used super.display() to refer to the parent class display function.

8. You added images to all the other objects in the game by modifying their class blueprint.

```
class Box extends BaseClass {
  constructor(x, y, width, height){
   super(x,y,width,height);
  this.image = loadImage("sprkt@ywood1.png");
}

7 }:
```

```
class Pig extends BaseClass {
constructor(x, y){
super(x,y.50.50);
this.image = loadImage("sprites/enem log");
}
```

```
class Log extends BaseClass(
constructor(x,y,hethot.angle){
super(x,y,20,h)(ght.angle);
this.image loadImage("sprites/wood2.png");
Matter.Body.setAngle(this.body, angle);
}

8
```

9. You added the background image in the sketch file.

```
HER LUNGSTU. 100, 200, PAILS.
           box5 = new Box(810,160,70,70);
           log4 - new Log(760,120,150, PI/7);
           log5 - new Log(870,120,150, -PI/7);
36
37
38
39
40
           bird - new Bird(100,100);
      function draw(){
       packground(backgroundImg):
           Engine.update(engine):
           console.log(box2.body.position.x);
          console.log(box2.body.position.y);
console.log(box2.body.angle);
45
46
47
48
49
50
51
52
           box1.display(); X box2.display(); X
           ground.display();
           pig1.disglay():
log1.display():
           bgw3.display():
          (box4.display():
           pig3.display();
           log3.display():
           box5.display();
           log4.display();
           log5.display():
           bird.display();
```

#### What's NEXT?

In the next class, you will learn about Git and GitHub.

# **EXTEND YOUR KNOWLEDGE:**
